AUTO TICKET CLASSIFICATION USING FLOW DESIGNER

1. PHASE 1: BRAINSTORMING & IDEATION PHASE

Project Idea

Auto Ticket Classification using Flow Designer is a Service Now project that automatically identifies the type/category of an incoming support ticket and classifies it based on the ticket information.

Instead of manually checking every ticket, Flow Designer can analyze the ticket details and automatically assign the appropriate cla***ssification.***

Problem Statement

IT Service Management (ITSM) operations face significant bottlenecks due to manual ticket categorization, prioritization, and routing. Modern IT helpdesks receive thousands of support requests daily across diverse categories—ranging from hardware failures and network connectivity issues to software access requests. Manual triage by helpdesk agents leads to:

i. High average time to acknowledge (TTA) and time to resolve (TTR).
ii. Frequent misrouting of tickets, causing unnecessary transfers between support groups.
iii. Operational inefficiency and high labor costs for initial level 1 (L1) triage.
iv. Human error in setting appropriate priority and urgency levels.
v. Manual routing delays: Support staff manually read and assign each incoming ticket, leading to wasted time

vi. .Uneven workloads: Some teams receive too many tickets while others sit idle due to lack of automated tracking

vii. Human error: Incorrect manual categorization results in bounced tickets and slower resolution times.

In a Service Now environment, many support tickets are created every day. Manual classification can:

- Take more time
- Cause incorrect categorization
- Delay ticket assignment
- Increase the workload of support teams

Proposed solution:

Create an automated Flow Designer workflow that checks ticket information and classifies the ticket according to predefined conditions

An automated ticket classification engine built using Service Now Flow Designer. The solution leverages event-based triggers, decision rules, and automated workflow logic to instantly analyze incoming incident details, accurately classify category and subcategory, set appropriate urgency and impact, and assign tickets to the correct support team without manual intervention.

Application

Instant Incident Routing:

Automatically assigns IT incidents (e.g., “VPN disconnected”, “Password reset required”) to the correct service desk tier based on keywords

SLA-Based Prioritization:

Identifies high-priority words (e.g., “Outage”, “Production down”, “CEO”) and automatically upgrades the ticket’s impact, urgency, and routing priority

Customer Service Sorting:

Parses external customer emails or portal submissions to categorize requests into technical support, billing queries, or account management

Security Incident Escalation:

Segregates potential security risks (e.g., “Phishing email”, “Unauthorized access attempt”) and immediately routes them to the Security Operations Center (SOC) while restricting standard visibility

VIP User Handling:

Detects tickets submitted by executive leadership or critical business units and routes them to a dedicated VIP support queue for expedited handling.
