AUTO TICKET CLASSIFICATION USING FLOW DESIGNER

PROJECT DEVELOPMENT PHASE

Introduction

The Project Development Phase is the stage where the planned requirements are converted into an actual working solution. In this project, "Auto Ticket Classification using Flow Designer" is developed using the ServiceNow platform. The main purpose of the development phase is to automatically identify the type of IT support ticket and assign the appropriate Category and Subcategory without requiring manual intervention from the IT support staff.

In the existing manual process, students or staff create an IT support ticket by entering the caller name and a short description of the issue. The support team then reads the description, understands the problem, and manually selects the appropriate category and subcategory. This process requires additional time and may sometimes result in incorrect classification.

To overcome this problem, a Flow Designer automation is created. The flow automatically checks the short description entered by the user and searches for predefined keywords. Based on the identified keyword, the flow updates the corresponding Category and Subcategory fields.

Flow Development

The flow is created using ServiceNow Flow Designer, which provides a low-code/no-code environment for creating business process automation.

The flow is designed with an appropriate trigger that starts the automation when a new IT support ticket is created. After the ticket is created, the flow obtains the ticket information and checks the short description.

The project uses the following classification logic:

- If the description contains "WiFi", the Category is assigned as Network and the Subcategory is assigned as WiFi.
- If the description contains "Projector", the Category is assigned as Hardware and the Subcategory is assigned as Projector.
- If the description contains "Password" or "Login", the Category is assigned as Access and the Subcategory is assigned as Forgot Password.
- If the description contains "Slow" or "Hanging", the Category is assigned as Performance and the Subcategory is assigned as Slow Computer.

These conditions are implemented inside the Flow Designer using conditional logic.

Record Update

After identifying the appropriate keyword, the flow updates the ticket record automatically. The Category and Subcategory values are populated according to the predefined rules.

For example, when a student creates a ticket with the description “WiFi is not connecting in the computer lab”, the flow identifies the keyword “WiFi”. It then automatically sets:

Category = Network

Subcategory = WiFi

Similarly, if the description is “Projector is not working”, the flow identifies “Projector” and assigns:

Category = Hardware

Subcategory = Projector

This reduces the need for IT staff to manually classify every ticket.

Development Outcome

The development phase results in a functional automated ticket-classification workflow. The solution is simple, maintainable, and can be extended with additional keywords and categories in the future.

The use of Flow Designer also reduces dependency on custom coding. Administrators can modify the flow conditions and actions according to future requirements.
