AUTO TICKET CLASSIFICATION USING FLOW DESIGNER

PROJECT DOCUMENTATION PHASE

Introduction

The Project Documentation Phase involves recording the complete development process of the Auto Ticket Classification using Flow Designer project. Proper documentation is important because it helps users, administrators, and future developers understand how the system works.

The documentation includes the project problem statement, objectives, requirements, development process, Flow Designer configuration, testing procedure, results, and demonstration details.

Project Problem Documentation

The project begins by documenting the existing problem in the school IT helpdesk. The helpdesk receives different types of requests such as WiFi issues, projector problems, password or login problems, and slow computers.

Previously, IT staff had to manually read each ticket and select the appropriate Category and Subcategory. This process can consume time and may result in classification errors.

The documentation explains how the proposed automated solution addresses this problem.

Technical Documentation

The technical documentation describes the Flow Designer implementation.

The major components documented are:

Flow Name: Auto Classify School IT Tickets

Application: Global

Trigger: New IT support ticket creation

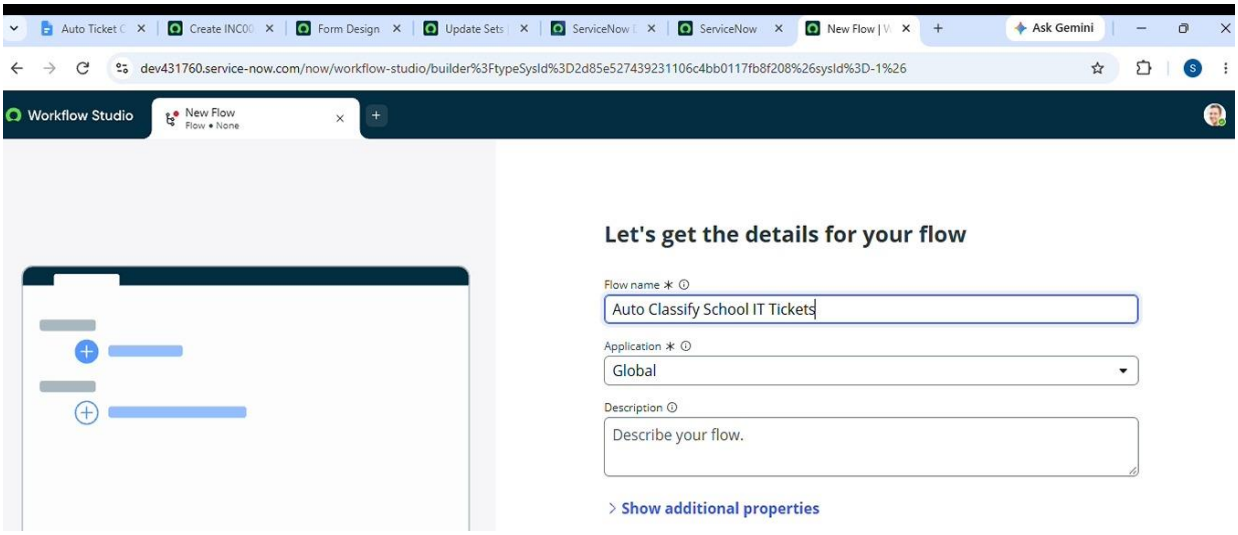

Input: Caller Name and Short Description

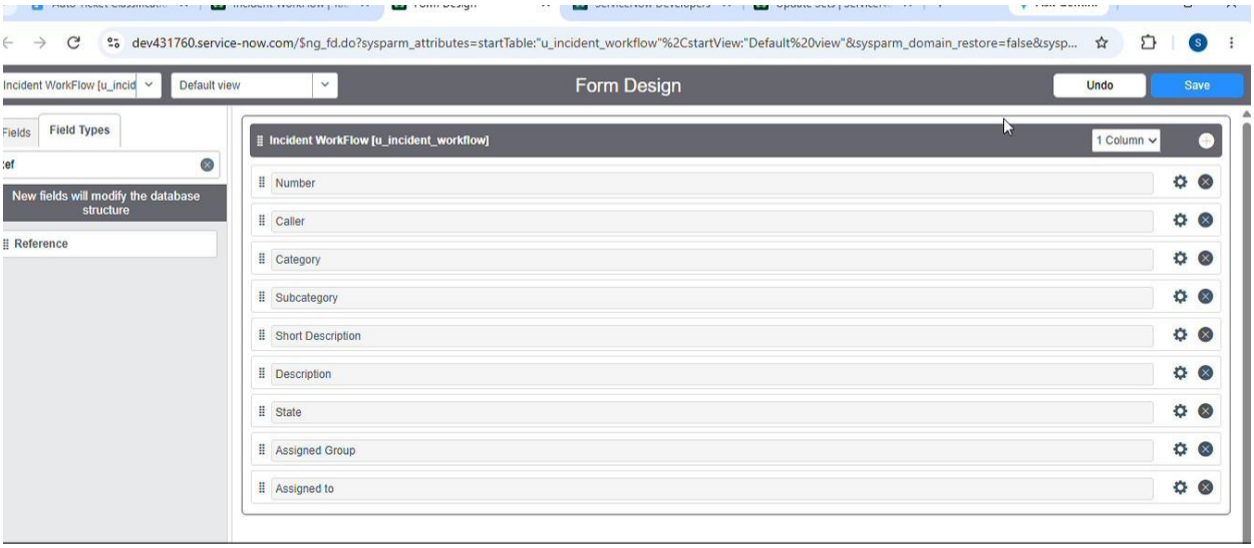

Condition: Keyword identification

Action: Update Category and Subcategory

Output: Automatically classified ticket

The keyword-to-category mapping is also documented clearly so that the flow can be maintained easily.

User and Process Documentation

The documentation also explains how a student or staff member creates a ticket. The user only needs to provide the required information such as Caller Name and Short Description.

The user does not need to manually select the Category or Subcategory because the Flow Designer handles the classification automatically.

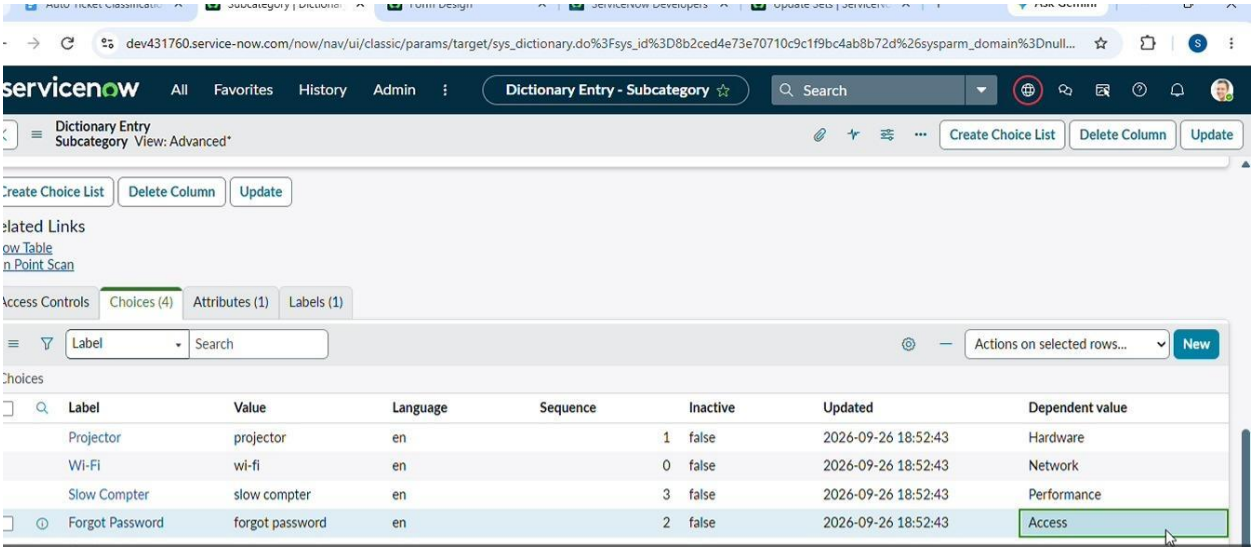

Screenshots of the Flow Designer configuration, ticket creation, and resulting classified tickets can be included in the project documentation.

Maintenance and Future Enhancement

The documentation also describes possible future enhancements. Additional keywords and categories can be added to the flow as new IT support requirements arise.

For example, future versions can include keywords related to software installation, printer issues, email problems, or network connectivity.

Therefore, the documentation provides a complete reference for understanding, maintaining, and improving the project.

Conclusion

The Auto Ticket Classification using Flow Designer project successfully demonstrates how automation can improve the process of managing and classifying service tickets in Service Now. The system automatically identifies and categorizes incoming tickets based on predefined conditions and routes them to the appropriate category or process.

By using Service Now Flow Designer, the project reduces manual effort, saves time, improves ticket accuracy, and provides a more organized workflow for handling service requests. The automated process also helps in faster ticket processing and reduces the possibility of human errors.

Overall, this project provides a practical solution for efficient ticket management and demonstrates how workflow automation can improve productivity and service delivery in an organization. The

project can be further enhanced by integrating AI-based classification, advanced automation, and real-time analytics for smarter and more efficient ticket management.
