AUTO TICKET CLASSIFICATION USING FLOW DESIGNER

PROJECT TESTING PHASE

Introduction

The Project Testing Phase is performed to verify whether the developed Flow Designer automation works correctly according to the project requirements. Testing ensures that tickets are classified correctly and that the appropriate Category and Subcategory values are automatically assigned.

The main objective of testing is to identify errors in the flow logic and ensure that the automation behaves as expected for different types of IT support requests.

Testing Method

Different sample IT support tickets are created with different short descriptions. Each ticket is used to verify whether the Flow Designer correctly identifies the keyword and updates the ticket.

The following test cases are used:

Test Case	Short Description	Expected Category	Expected Subcategory
TC01	WiFi is not working	Network	WiFi
TC02	Projector is not displaying	Hardware	Projector
TC03	Forgot Password	Access	Forgot Password
TC04	Login problem	Access	Forgot Password
TC05	Computer is very Slow	Performance	Slow Computer
TC06	Computer is Hanging	Performance	Slow Computer

Functional Testing

In functional testing, each condition in the flow is tested individually. For example, a ticket containing the word “WiFi” is created. The flow is triggered and checks the short description. When the keyword is identified, the flow updates the Category to Network and Subcategory to WiFi.

The same process is repeated for Projector, Password, Login, Slow, and Hanging keywords. The test results are checked by opening the created ticket and verifying the automatically populated fields.

Error and Exception Testing

The project also considers descriptions that do not contain any of the predefined keywords. Such tickets should not be incorrectly assigned to an unrelated category.

This type of testing helps ensure that the flow does not produce unwanted classification results. Testing also verifies whether the flow is triggered correctly whenever a new ticket is created and whether the record is updated without manual intervention.

Testing Result

The testing phase confirms that the Flow Designer logic can automatically classify tickets according to the predefined conditions. The results demonstrate that the automation can reduce manual classification work and provide consistent ticket categorization.

Testing also provides confidence that the developed solution satisfies the main project objectives.
